Aurélien CRIDA

EXOPLANETS

Giordano Bruno said that the many stars are like our Sun, with planets like our Earth, inhabited as well (in *de l'infinito universo e mondi* (1574)). He was burnt alive for this claim.

Modern sciences : We expect stars to form together with a protoplanetary disk, in which planets form, but we hadn't seen them, until :

Mayor & Queloz (1995) detected
« *A Jupiter-mass companion to a solar-type star* »

They exist !

This is a revolution of our vision of the Universe.

EXOPLANETS

I Detection methods

- Radial velocity (velocimetry)
- Transit (photometry)
- Micro-lensing (photometry)
- Astrometry
- Direct imaging

II Properties and statistics

- Mass, semi major axis, period, eccentricity, radius, metallicity of the host star, density, spectrum...

EXOPLANETS Ia) Radial velocity

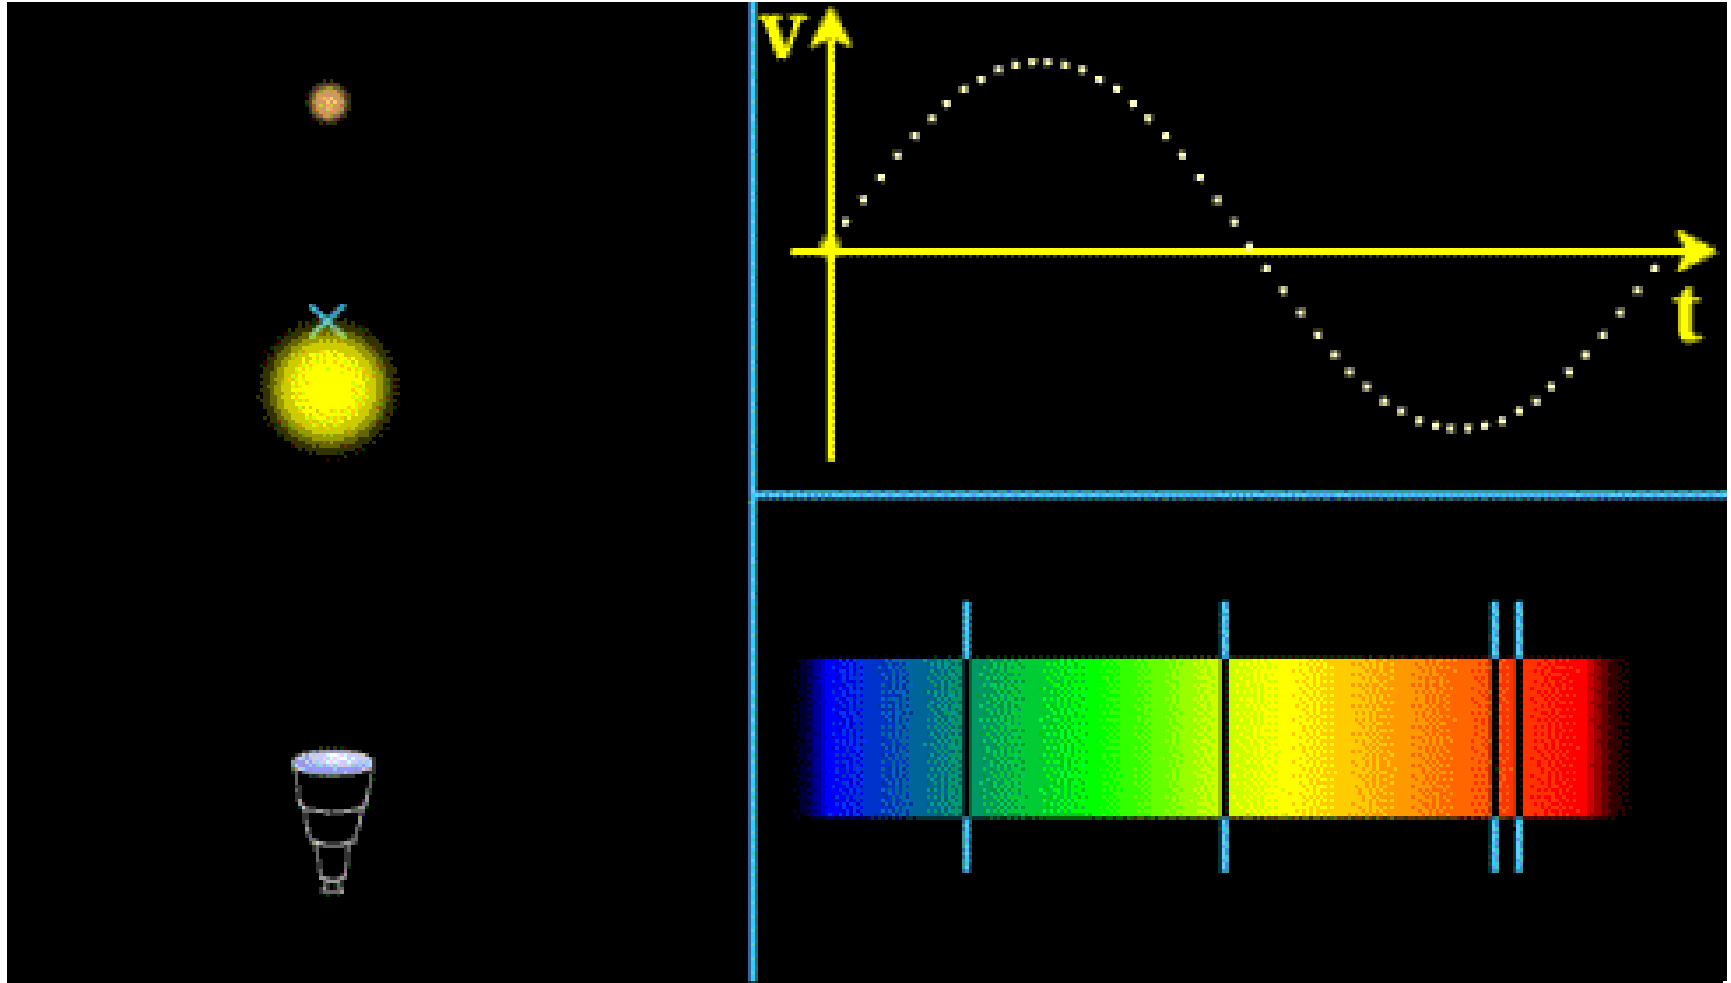

The Radial Velocity Method

ESO Press Photo 22e/07 (25 April 2007)

This image is copyright © ESO. It is released in connection with an ESO press release and may be used by the press on the condition that the source is clearly indicated in the caption.

EXOPLANETS Ia) Radial velocity

EXOPLANETS Ia) Radial velocity

Example : HD189733

EXOPLANETS Ia) Radial velocity

Example : HD189733

EXOPLANETS Ia) Radial velocity

Example : GJ876b : an eccentric orbit.

EXOPLANETS Ia) Radial velocity

The **semi major axis** a is given by the period :

$$T^2 = (4\pi^2/GM_*)a^3$$

The **mass** $q=M_p/M_*$ is given by the amplitude δv :

$$\text{The velocity of the planet is : } v_p = a\Omega = (GM_*/a)^{1/2}$$

Thus the velocity of the star around the centre of mass is, by conservation of the momentum : $v_* = -q v_p$

$$\text{Thus: } q = \delta v (a/GM_*)^{1/2}.$$

Numerical application : (reminder: $M_{\text{Sun}}=2.10^{30}$ kg)

For Jupiter, $q=10^{-3}$, $a=5,2$ UA, $\delta v = 13$ m.s⁻¹.

For the Earth, $q=3.10^{-6}$, $a=1$ UA, $\delta v = 0,09$ m.s⁻¹.

EXOPLANETS Ia) Radial velocity

EXERCICE :

HD189733b :

One gives

$T=2,218$ days,

$M_* = 1,6 \times 10^{30}$ kg.

Find q , M_p .

EXOPLANETS Ia) Radial velocity

EXERCICE :

HD189733b :

One gives

$T=2,218$ days,

$M_* = 1,6 \times 10^{30}$ kg.

Find q , M_p .

SOLUTION :

$a = 4,64 \times 10^9$ m = 0.031 AU . $\delta v = \sim 200$ m.s⁻¹.

Thus $q = 1,3 \times 10^{-3}$, so $M_p = 1,1 M_{Jup}$.

EXOPLANETS Ia) Radial velocity

Caution !

The measured velocity is actually $qa_p \Omega_p \sin(i)$,

where i is the angle between the line of sight and the axis of the orbit.

$i=0^\circ$: seen face-on, planet undetectable.

$i=90^\circ$: seen edge-on, optimal case.

The obtained mass is actually $M_p \sin(i)$, where i is unknown !

On average, $1/\sin(i)$ is $\pi/2$.

EXOPLANETS Ia) Radial velocity

Nowadays (2012) differences in velocity of the order of a few 0.1 m/s can be measured ! It corresponds to a difference in λ smaller than the width of a spectral line (remind $\delta\lambda = \lambda_0 v/c$).

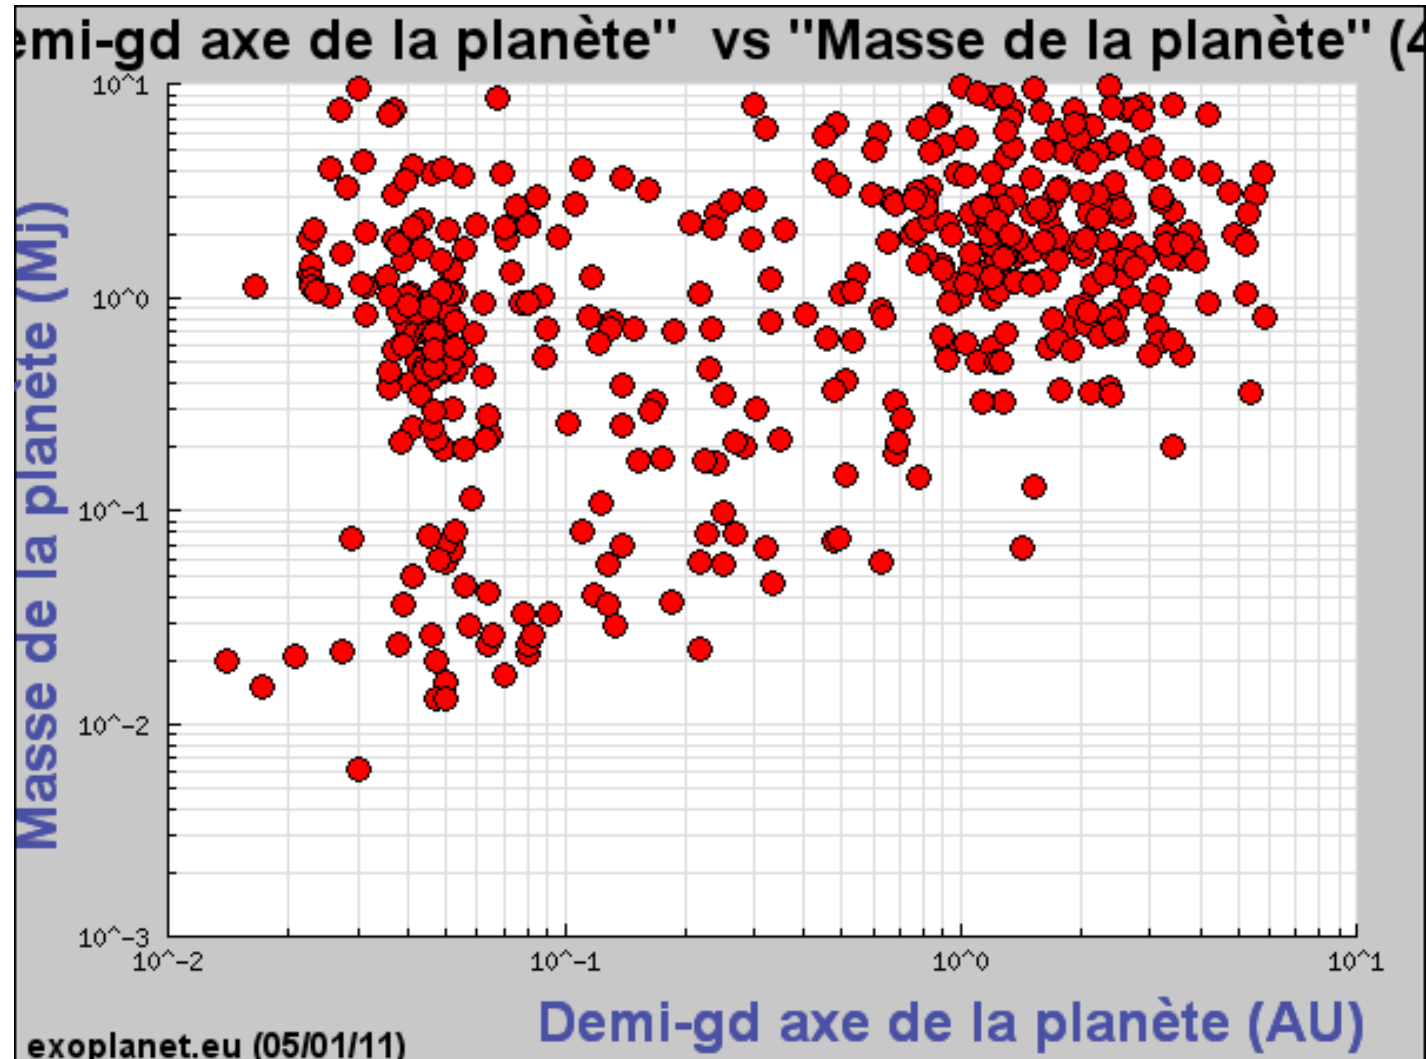

Detectability :

It is much easier to detect a giant planet close to its star.

EXOPLANETS Ia) Radial velocity

Detections : The 484 planets detected the 5/1/2011.

EXOPLANETS Ia) Radial velocity

Detections : Time evolution of the detection rate.

EXOPLANETS : Ib) Transit

EXOPLANETS : Ib) Transit

Like Venus in front of the Sun in 2004 and 2012, sometimes, an exoplanet moves in front of its star, this is a **transit**.

Then, one sees a decrease of the luminosity of the star :

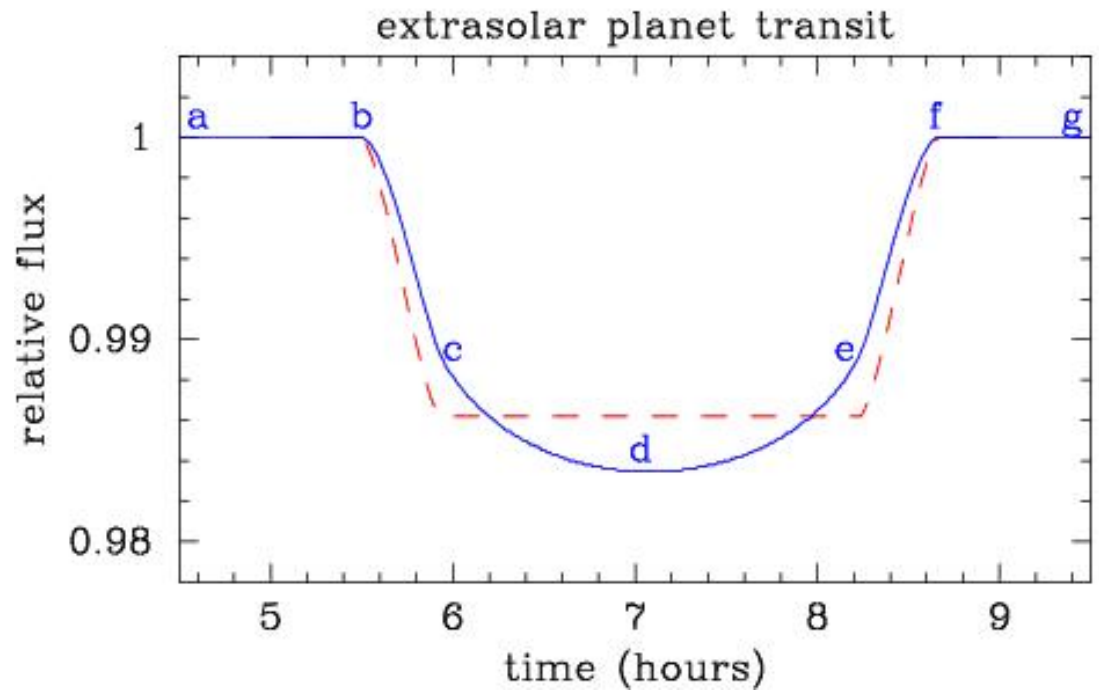

EXOPLANETS : Ib) Transit

Limb darkening effect : the bottom of the transit isn't flat.

A transit lasts a few hours.

EXOPLANETS : Ib) Transit

Ex: HD 189733b, seen in radial velocity, also has a transit :

EXOPLANETS : Ib) Transit

A planetary transit should be periodic.

Ex: light curve of a star observed by Corot :

EXOPLANETS : Ib) Transit

Corot : COnvection ROtation, et Transits planétaires.

satellite of the CNES (70%), launched on 26/12/06, which tracks luminosity variations of thousands of stars during many months in a row.

Ex: The first exoplanet discovered by Corot:

Copyright Corot

EXOPLANETS : Ib) Transit

Other transit detection projects :

Kepler (NASA), launched on 7/3/09.
already 1200 planet candidates !
But only candidates...

A-STEP : Antarctica Search for Transiting Extrasolar Planets,
automatic telescope of 40cm at Dome C, at Concordia
(University of Nice)

EXOPLANETS : Ib) Transit

Advantages of the transit method :

The amplitude of the transit gives the radius of the planet :

$$\delta L/L = \pi r_p^2 / \pi r_*^2 = (r_p/r_*)^2$$

The period of the transit gives the semi major axis (Képler's law).

The radial velocity gives the real mass : $i=90^\circ$.

One derives the density of the planet !

EXOPLANETS : Ib) Transit

Advantages of the transit :

Possible surprises...

Ex: HD209458b :

huge absorption in Ly α
during the transit, as if
an atmosphere of H
large as $\sim r_p/3$

surrounding the planet.

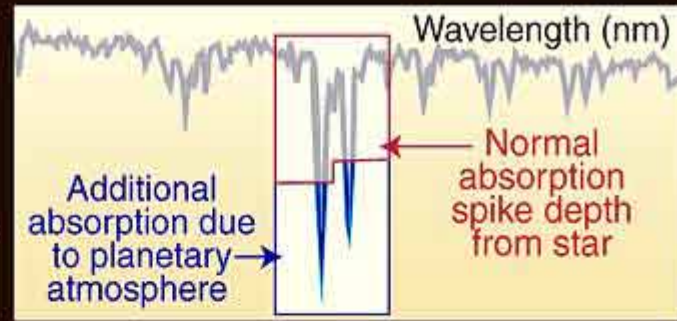

EXOPLANETS : Ib) Transit

Advantages of the transit method :

If the atmosphere of the planet makes absorption lines, composition !

HST detects additional sodium absorption due to light passing through planetary atmosphere as planet transits across star

EXOPLANETS : Ib) Transit

Conditions for a transit :

The planet must pass in front of the star.

Condition on i ?

EXOPLANETS : Ib) Transit

Conditions for a transit :

The planet must pass in front of the star, that is :

$$|\pi/2 - i| < \arcsin(r_*/a_p) \quad \text{ou:} \quad a_p < r_*/|i - \pi/2| \quad (\text{pour } i \sim \pi/2)$$

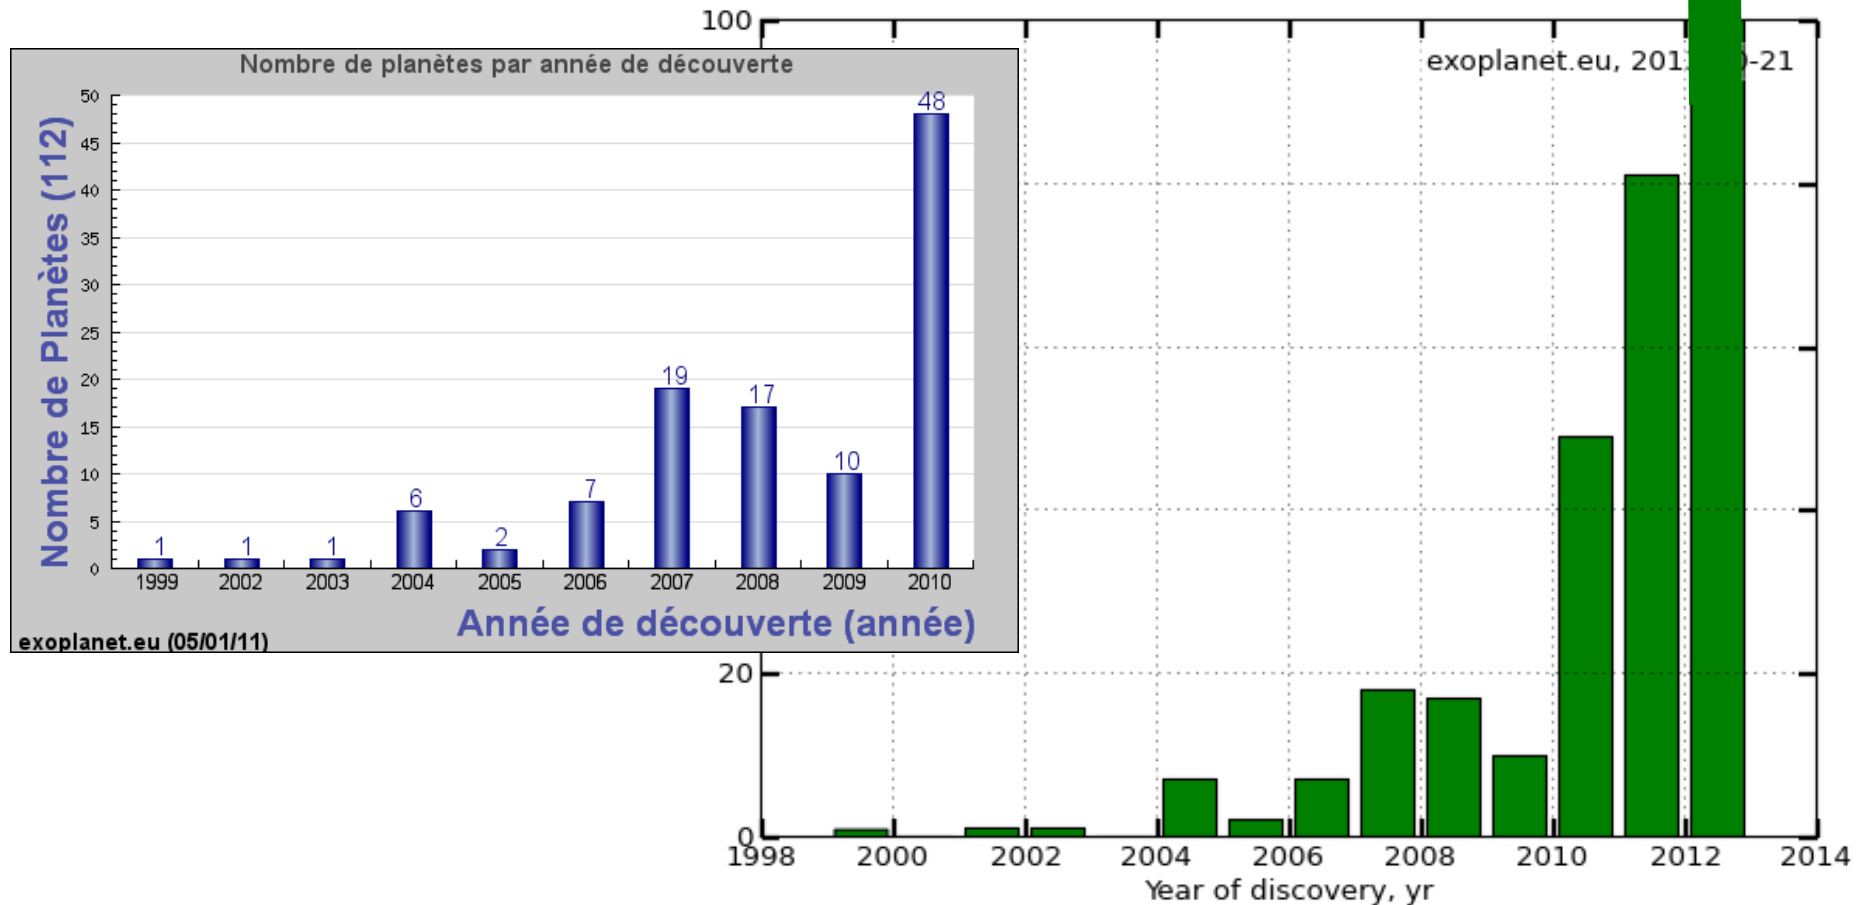

Short period planets are favoured.

EXOPLANETS : Ib) Transit

Detections :

112 planets at 1/1/11 detected by transit, and confirmed by velocimetry. Many more since (Corot + Kepler)...

EXOPLANETS : Ib') Secondary transit

When the planet goes behind its star, its light is masked. By subtraction, one can (almost) find the spectrum of the planet, thus its temperature...

EXOPLANETS : Ib') Secondary transit

EXOPLANETS : I c) Microlensing

Gravitational lense :

When a star passes exactly in front of an other star, it deviates the light rays, like a lense (Einstein). One sees a peak in the luminosity.

A secondary peak betrays the presence of a planet.

The luminosity of stars in the core of the Milky Way is followed carefully (dense region).

EXOPLANETS : I c) Microlensing

Spotting distant Earth-like planet

Discovery of distant Earth-like planet was made using a method called microlensing, which can detect far-off planets without actually seeing the object.

When a massive object crosses in front of a star shining in the background, the front star's gravity bends light rays from distant star and magnifies them like a lens:

What astronomers see

A magnification of light of distant star:

Times brighter than normal shine

1 First observed change of light was the passing of the front star

2 The way the distant star's light changed again, betrays the Earth-like planet's presence

Earth-like planet

When planet passes, an additional distortion of the light occurs

3 Computer analysis calculates planet's size and likely characteristics:

Size: Only five times as massive as Earth

Surface: Likely to be rocky/icy

Atmosphere: Likely to have a thin atmosphere

Temperature: Its relative cool parent star implies a surface temperature of -364°F (-220°C)

EXOPLANETS : I c) Microlensing

Light Curve of OGLE-2005-BLG-390

EXOPLANETS : I c) Microlensing

Big planets far from their host stars are favoured.

Drawbacks:

We don't see the host star.

Unique observation, not periodic, impossible to redo.

Orbital parameters unknown (only the distance to the host star times $\sin(i)$ at one moment is known).

Total :

24 detections upto 2013.

EXOPLANETS : I d) Astrometry

The star is directly seen orbiting around the centre of mass, on the background of distant stars.

Caution : parallax and proper movement of the star add up to the orbit around the centre of mass.

Bright future for this technique, with GAIA : precision astrométry.

Advantages :

One gets directly i , a_p , e_p , M_p .

EXOPLANETS : I e) Direct imaging

The planet is directly observed around the star, which can be shut down by a coronagraph if needed.

First ever image of an
extra-solar planet :
Chauvin et al. (2004)

Or is it a double brown dwarf ?

EXOPLANETS : I e) Direct imaging

Fomalhaut b

(Kalas et al., 2008, Science)

EXOPLANETS : I e) Direct imaging

HR8799 :

3 giant planets
at 24, 38, et 68
AU from the
star.

(Marois et al.,
2008, Science)

+ 1 fourth one
confirmed in
november 2010

EXOPLANETS : I e) Direct imaging

Total : 32 planets detected this way (at the end of 2012).

This method favors giant planets, far from their stars, which are not accessible by velocimetry or transits.

Needs for refined observations techniques (interferometry, coronagraphy, ...).

Advantages:

Direct proof of existence

Possibility of spectroscopy...

EXOPLANETS : I Detections summary

The number of detections per year seems to grow exponentially :

Life is in logscale...

I Detection methods

- Radial velocity (velocimetry)
- Transit (photometry)
- Micro-lensing (photometry)
- Astrometry
- Direct imaging

II Properties and statistics

- Mass, semi major axis, period, eccentricity, radius, metallicity of the host star, density, spectrum...

EXOPLANETS : II) Statistics

We don't have only 1 system at hand, but hundreds ! The planetary formation models must take this diversity into account, and explain the observed properties.

Caution : every method has its biases.

Be aware of that when doing statistics.

EXOPLANETS : II) Statistics

Nowadays (2012) differences in velocity of the order of a few 0.1 m/s can be measured ! It corresponds to a difference in λ smaller than the width of a spectral line (remind $\delta\lambda = \lambda_0 v/c$).

Detectability :

$$\delta v = q (GM_*/a)^{1/2}.$$

It is much easier to detect a giant planet close to its star.

EXOPLANETS : II) Statistics

EXOPLANETS : II) Statistics

EXOPLANETS : II) Statistics

EXOPLANETS : II) Statistics

In spite of observational biases, one sees 3 populations, separated by 2 deserts.

EXOPLANETS : II) Statistics

The desert between neptune mass planets and Jupiter mass planets is consistent with the core accretion model for the formation of giant planets : the growth from Neptune mass to Jupiter mass is extremely fast.

Either the disk life-time is enough to form a Jupiter-like gas giant, or it isn't, and one only gets an icy core with smaller atmosphere, like Neptune

EXOPLANETS : II) Statistics

Statistics in period suggest that migration plays a big role...
but not always !

EXOPLANETS : II) Statistics

Strong influence of the metallicity of the host star !

The likelihood of the presence of planet(s) increases with Z .

Why ?

EXOPLANETS : II) Statistics

Excentricities : great variety !

EXOPLANETS : II) Statistics

Correlation $a - e$?

EXOPLANETS : II) Planet Population Synthesis

Planet Population Synthesis :

Kitchen recipe including all the ingredients we have seen in the *planet formation* Chapter :

accretion, disk evolution, migration, and so on.

Programm the evolution of 1 embryo, starting from an initial mass and semi-major axis.

Repeat this operation for a whole distribution of initial conditions.

Look at the final distribution.

Compare with the statistics of the observations.
